## Why do we have so many real-time TDDFT codes?

and many more....

# Part 1: Density Functional Theory

## How to do Kohn-Sham Density Functional Theory?

#### Kohn-Sham equations

$$egin{split} \left[-rac{1}{2}
abla^2+v_{ ext{ext}}(m{r})+v_{ ext{H}}[n](m{r})+v_{ ext{xc}}[n](m{r})
ight]arphi_i(m{r})&=\epsilon_iarphi_i(m{r})\ n(m{r})&=\sum_{i=1}^N|arphi_i(m{r})|^2 \end{split}$$

- ${\, \bullet \, }$  We need to choose an approximation for  $v_{\rm xc}[n]$
- ${\, \bullet \, }$  We need to solve a Poisson equation to get  $v_{\rm H}[n]$

## How to do Kohn-Sham Density Functional Theory?

Time-dependent Kohn-Sham equations for noncollinear magnetism

$$\begin{split} i\partial_t \varphi_i(\boldsymbol{r},t) &= \left[ (-\frac{1}{2} \nabla^2 + v_{\text{ext}}(\boldsymbol{r},t) + v_{\text{H}}[n](\boldsymbol{r},t) + v_{\text{xc}}[n,\mathbf{m}](\boldsymbol{r},t))\sigma_0 \right. \\ &+ \frac{1}{2c} \mathbf{B}_{\text{xc}}[n,\mathbf{m}](\boldsymbol{r},t) \cdot \boldsymbol{\sigma} + \frac{1}{4c^2} \boldsymbol{\sigma} \cdot (\nabla v_s(\boldsymbol{r},t) \times -i\nabla) \right] \varphi_i(\boldsymbol{r},t) \\ &n_{\sigma,\sigma'}(\boldsymbol{r}) = \sum_{i=1}^N \sum_{\sigma=\uparrow,\downarrow} \varphi_{i,\sigma}(\boldsymbol{r}) \varphi_{i,\sigma'}^*(\boldsymbol{r}) \end{split}$$

• We need to choose an approximation for  $v_{\rm xc}[n]$ need to solve a Poisson equation to get  $v_{\rm H}[n]$

## How to do Kohn-Sham Density Functional Theory?

#### Kohn-Sham equations

$$\begin{bmatrix} -\frac{1}{2}\nabla^2 + v_{\text{ext}}(\boldsymbol{r}) + v_{\text{H}}[n](\boldsymbol{r}) + v_{\text{xc}}[n](\boldsymbol{r}) \end{bmatrix} \varphi_i(\boldsymbol{r}) = \epsilon_i \varphi_i(\boldsymbol{r})$$
$$n(\boldsymbol{r}) = \sum_{i=1}^N |\varphi_i(\boldsymbol{r})|^2$$

 $\bullet\,$  It is a boundary value problem  $\rightarrow\,$  We need to specify the boundary conditions

- For finite systems, functions go to zero away from the center of mass of the system:
  - Force functions to go to zero on the border of the simulation box
  - The box has to be large enough to contain the functions
- Other BCs are possible:
  - periodic (Born-von Kármán)
  - zero derivative
  - absorbing
  - semi-periodic
  - etc

We need to know the total electronic density

$$n(oldsymbol{r}) = \sum_{i=1}^N ert arphi_i(oldsymbol{r}) ert^2 \;.$$

And hence we need to know the Kohn-Sham wavefunctions  $\rightarrow$  Freedom in the choice of representations, as long as a (complete) basis is used !

- Real-space sampling, splines, ...
- Boundary-condition adapted basis (planewaves, localized orbitals)

Most of the TDDFT codes have different basis for expression the wavefunctions.

The basis also affect the calculation of the Laplacian, but also the forces.

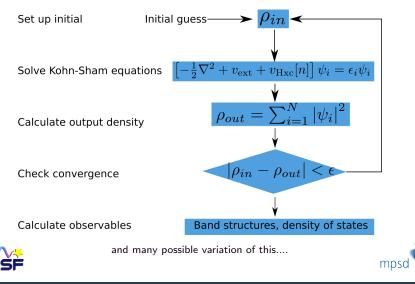

#### Kohn-Sham equations

$$\begin{bmatrix} -\frac{1}{2}\nabla^2 + v_{\text{ext}}(\boldsymbol{r}) + v_{\text{H}}[n](\boldsymbol{r}) + v_{\text{xc}}[n](\boldsymbol{r}) \end{bmatrix} \varphi_i(\boldsymbol{r}) = \epsilon_i \varphi_i(\boldsymbol{r})$$
$$n(\boldsymbol{r}) = \sum_{i=1}^N |\varphi_i(\boldsymbol{r})|^2$$

- $\bullet\,$  It is a boundary value problem  $\rightarrow\,$  We need to specify the boundary conditions
- A self-consistency scheme is used to treat the non-linearity
- Solve for eigenstates at fixed  $v_{\mathrm{Hxc}}$ , then update n and  $v_{\mathrm{Hxc}}$

## Self-consistent field calculation

- ${ullet}$  Do we need all the electrons?  $\rightarrow$  all electrons vs pseudopotentials
- $\bullet\,$  Do you care about spin-degrees of freedom?  $\to$  collinear or non-collinear spin-DFT

- ullet Boundary-value problem ightarrow the boundaries need to be specified
- Representation of the wavefunctions need to be chosen
- An algorithm to achieve self-consistency need to be specified (mixing, preconditioning, subspace diagonalization, convergence criteria, ...).

## Part 2: Time-dependent Density Functional Theory

## Time-dependent Density Functional Theory

#### Time-dependent Kohn-Sham equation

$$\mathbf{i}\frac{\partial}{\partial t}\varphi_i(\boldsymbol{r},t) = \left(-\frac{1}{2}\nabla^2 + v_{\text{ext}}(\boldsymbol{r},t) + v_{\text{Hxc}}[n,\Psi_0,\Phi_0](\boldsymbol{r},t)\right)\varphi_i(\boldsymbol{r})$$
$$n(\boldsymbol{r},t) = \sum_{i=1}^N |\varphi_i(\boldsymbol{r},t)|^2$$

- $\bullet$  We need to choose an approximation for  $v_{\rm xc}[n] \to$  adiabatic approximation used almost all the time
- ${\, \bullet \,}$  We need to solve a Poisson equation to get  $v_{\rm H}[n]$

Time-dependent Kohn-Sham equation

$$\mathbf{i}\frac{\partial}{\partial t}\varphi_i(\mathbf{r},t) = \left(-\frac{1}{2}\nabla^2 + v_{\text{ext}}(\mathbf{r},t) + v_{\text{Hxc}}[n,\Psi_0,\Phi_0](\mathbf{r},t)\right)\varphi_i(\mathbf{r})$$
$$n(\mathbf{r},t) = \sum_{i=1}^N |\varphi_i(\mathbf{r},t)|^2$$

- It is an initial value problem
- Usually the ground-state is used as initial state  $v_{\rm Hxc}[n, \Psi_0, \Phi_0] \rightarrow v_{\rm Hxc}[n]$
- Various numerical schemes for doing the time-propagation

Propagation of the wavefunctions in time:

$$\varphi_i(\boldsymbol{r},t') = \hat{T} \exp\left\{-\mathrm{i} \int_t^{t'} \mathrm{d}\tau \, \hat{H}(\tau)\right\} \varphi_i(\boldsymbol{r},t)$$

which means

$$\varphi_i(\boldsymbol{r},t') = \left\{ \sum_{n=0}^{\infty} \frac{(-i)^n}{n!} \int_t^{t'} \mathrm{d}\tau_1 \dots \int_t^{t'} \mathrm{d}\tau_n \, \hat{T}\hat{H}(\tau_1) \dots \hat{H}(\tau_n) \right\} \varphi_i(\boldsymbol{r},t)$$

If the Hamiltonian commutes with itself at different times, we can drop the time-ordering product and we have

$$\varphi_i(\boldsymbol{r},t') = \exp\left\{-\mathrm{i}(t'-t)\hat{H}\right\}\varphi_i(\boldsymbol{r},t)$$

Not the case in TDDFT is we have external time-dependent perturbations fluctuations of the electronic density.

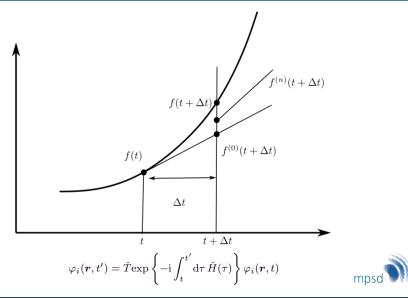

Solution: split the propagation into short-time propagation using the composition property:

$$U(t',t) = U(t',\tau)U(\tau,t), \quad t' \ge \tau \ge t \quad \to \quad U(t',0) = \prod_{i=0}^{N-1} U(t_i + \Delta t, t_i)$$

## A practical scheme for the time propagation

The orbitals  $\varphi_j(t + \Delta t)$  are computed from the knowledge of  $\varphi_j(\tau)$  and  $H(\tau)$  for  $0 \le \tau \le t$ .

• Approximation  $H(\tau)$  if we need for example  $\tau$  in between t and  $t + \Delta t$ 

• Propagate 
$$\varphi_j(t)$$
 to get  $\varphi_j(t + \Delta t)$ 

- Calculate  $H(t+\Delta t)$  from the orbitals  $\varphi_j(t+\Delta t)$
- Interpolate the required  $H(\tau)$  from H(t) and  $H(t+\Delta t)$
- Repeat steps 2-4 until self consistency is reached

In practice, simpler schemes are usually used and self-consistency is often neglected. Instead, we rely on a sufficiently small  $\Delta t.$ 

The exponential mid-point propagator is given by

$$U(t + \Delta t, t) \approx U_{EM}(t + \Delta t, t) = \exp\left\{-i\Delta t \hat{H}(t + \Delta t/2)\right\}$$

Well grounded theoretically:

- Unitary (if the exponential is properly computed)
- Preserves time-reversal symmetry (if the self-consistency is achieved)

If the Hamiltonian matrix can be stored in memory, one can compute exactly  $\exp\{H\}$ .

If not, we need to approximate the exponential, e.g. using a Taylor expansion

$$\exp\{A\} = \sum_{k=0}^{\infty} \frac{1}{k!} A^k$$

Taylor expansion to fourth order seems to give good results for some TDDFT codes.

Other choices are possible: Chebyshev basis expansion, Krylov-subspace projection (Lanczos method), ...

- Initial value problem ightarrow the starting point needs to be specified
- An approximation to the time-evolution operator needs to be specified (exponential mid-point, Runge-Kutta, Magnus expansions, Crank-Nicolson method, ...).
- A method for computing the exponential is needed (Taylor, Chebyshev, Krylov,...)
- You might want to include self consistency
- $\bullet\,$  Do we want the ions to move?  $\to$  Ehrenfest dynamics? beyond Ehrenfest?
